Chapter 1

Introduction

This chapter describes the GAP package HERmitian. This package implements functionalities for divisors and Riemann-Roch spaces of an algebraic function field of Hermitian.

If you are viewing this with on-line help, type:

```
gap> ?HERmitian package
```

to see the functions provided by the HERmitian package.

1.1 Unpacking the HERmitian Package

If the HERmitian package was obtained as a part of the GAP distribution from the "Download" section of the GAP website, you may proceed to Section ??. Alternatively, the HERmitian package may be installed using a separate archive, for example, for an update or an installation in a non-default location (see (**Reference: GAP Root Directories**)).

Below we describe the installation procedure for the .tar.gz archive format. Installation using other archive formats is performed in a similar way.

To install the HERmitian package, download the package archive from the package webpage, unpack the archive file, which should have a name of form HERmitian-XXX.tar.gz for some version number XXX, by typing

```
gzip -dc HERmitian-XXX.tar.gz | tar xpv It may be unpacked in one of the following locations:
```

- in the pkg directory of your GAP 4 installation;
- or in a directory named . gap/pkg in your home directory (to be added to the GAP root directory unless GAP is started with -r option);
- or in a directory named pkg in another directory of your choice (e.g. in the directory mygap in your home directory).

In the latter case one one must start GAP with the -1 option, e.g. if your private pkg directory is a subdirectory of mygap in your home directory you might type:

```
gap -1 ";myhomedir/mygap"
```

where *myhomedir* is the path to your home directory, which (since GAP 4.3) may be replaced by a tilde (the empty path before the semicolon is filled in by the default path of the GAP 4 home directory).

1.2 Loading the HERmitian Package

To use the HERmitian Package you have to request it explicitly. This is done by calling LoadPackage (**Reference: LoadPackage**):

```
gap> LoadPackage("HERmitian");

Loading HERmitian 0.1
by Gábor P. Nagy (http://www.math.u-szeged.hu/~nagyg)
For help, type: ?HERmitian package

true
```

If GAP cannot find a working binary, the call to LoadPackage will still succeed but a warning is issued informing that the HelloWorld() function will be unavailable.

If you want to load the HERmitian package by default, you can put the LoadPackage command into your gaprc file (see Section (Reference: The gap.ini and gaprc files)).

1.3 Testing the HERmitian Package

You can run tests for the package by

```
gap> Test(Filename(DirectoriesPackageLibrary("HERmitian"),"../tst/testall.tst"));
```

Chapter 2

Mathematical background

Our notation and terminology are standard. The reader is referred to [HKT08], [Sti09]. For the decoding of algebraic-geometric codes see the survey paper [HP95].

2.1 Algebraic curves, places, divisors

An algebraic plane curve X over the field K is given by a polynomial $f(X,Y) \in K[X,Y]$ of degree n; the usual notation is X: f(X,Y) = 0. The *affine points* of X are pairs $(x,y) \in L^2$, where L is an extension field of K and f(x,y) = 0 holds. We say that (x,y) is a *smooth point* of X if $(\frac{\partial f}{\partial X}(x,y), \frac{\partial f}{\partial Y}(x,y)) \neq (0,0)$. At a smooth affine point $(x,y) \in L^2$, the curve has formal local parametrization $(\xi(t), \eta(t)) \in L[[t]]^2$ such that $\xi(0) = x$, $\eta(0) = y$ and $f(\xi(t), \eta(t)) = 0$. Non smooth points are called *singular*.

The affine curve X: f(X,Y)=0 has homogeneous equation F(X,Y,Z)=0 with $F(X,Y,Z)=Z^n f(\frac{X}{Z},\frac{Y}{Z})$. The projective points of X satisfy F(x,y,z)=0. In particular, the affine point (x,y) of $\mathscr X$ corresponds to a projective point (x:y:1). The points of X at infinity are given by the homogeneous equation F(X,Y,0)=0. Smoothness and local parametrization at projective points are defined in the obvious way. We say that the projective point (x:y:z) of X is defined over X if X is defined over an algebraic extension of the underlying field X.

The algebraic curve X is said to be *nonsingular* or *smooth*, if all its points are smooth. This implies that f is absolutely irreducible. For smooth algebraic plane curves, the concept of a *place* is equivalent with the concept of a point, when X is considered as a curve over the algebraic closure of K. A *divisor* is a formal sum $D = n_1P_1 + \ldots + n_kP_k$ with integers n_1, \ldots, n_k and places P_1, \ldots, P_k . The degree of P_1, \ldots, P_k is the integer P_1, \ldots, P_k . The integer P_1, \ldots, P_k is the *valuation* P_1, \ldots, P_k one has P_2, \ldots, P_k one has P_1, \ldots, P_k one has P_2, \ldots, P_k is the set of places P_1, \ldots, P_k such that P_2, \ldots, P_k one has P_1, \ldots, P_k one has P_2, \ldots, P_k one has P_3, \ldots, P_k one has P_4, \ldots

2.2 Function fields and Riemann-Roch spaces

Let X: f(X,Y) = 0 be a smooth plane algebraic curve. The function field K(X) of X is generated by the variables x,y subject to the algebraic relation f(x,y) = 0. In particular, each element of K(X) can be written as a(x,y)/b(x,y) with $a,b \in K[X,Y]$. Let $h \in K(X)$ and a place P of X, we define the valuation $v_P(h)$ as the subdegree of $h(\xi(t),\eta(t))$, where $(\xi(t),\eta(t))$ is the formal local parametrization at P. If $v_P(h) > 0$ then P is a zero of h, if $v_P(h) < 0$ then P is a pole of h. If $v_P(h) \ge 0$, then $h(P) = h(\xi(0),\eta(0))$ is a well-defined element of K.

For every non-zero function $h \in K(X)$, $\operatorname{Div}(h)$ stands for the principal divisor associated with h while $\operatorname{Div}(h)_0$ and $\operatorname{Div}(h)_\infty$ for its zero and pole divisor. Furthermore, for every separable function $h \in K(X)$, dh is the exact differential arising from h, and Ω denotes the set of all these differentials. Also, $\operatorname{res}_P(dh)$ is the residue of dh at a place of P of K(X).

For any divisor A of K(X), the Riemann-Roch space of A is

$$\mathcal{L}(A) = \{ h \in K(X) \setminus \{0\} | \operatorname{Div}(h) \succeq -A \} \cup \{0\}.$$

We denote $\ell(A) = \dim(\mathcal{L}(A))$. Furthermore, the *differential space* of *A* is

$$\Omega(A) = \{ dh \in \Omega \mid \text{Div}(dh) \succeq A \} \cup \{0\}.$$

Both the Riemann-Roch and the differential spaces are linear spaces over K. Their dimensions are given by the theorem of Riemann-Roch:

$$\ell(A) = \deg(A) + 1 - g + \ell(W - A).$$

Here, W is a canonical divisor of X, and g is the *genus* of X. The latter is the most important birational invariant of an algebraic curve. For smooth curves of degree n, the genus formula is

$$g = \frac{(n-1)(n-2)}{2}.$$

The theorem of Riemann-Roch implies

$$\ell(A) \ge \deg(A) + 1 - g$$

with equality if deg(A) > 2g - 2.

2.3 Automorphisms of algebraic curves

Let X: f(X,Y) = 0 be a smooth plane algebraic curve with function field K(X) = K(x,y), where the elements x,y are subject to the algebraic relation f(x,y) = 0. We assume that K is the constant field of K(X). An *automorphism* of X is an automorphism of the function field, leaving all elements of K fixed. In particular, for any automorphism α of X, there are polynomials $u, v, w \in K[X,Y]$ such that

$$\alpha: (x,y) \to \left(\frac{u(x,y)}{w(x,y)}, \frac{v(x,y)}{w(x,y)}\right).$$

Substituting formal power series in α , we obtain an action of α on the set of places of X. This extends to an action on divisors, differentials and Riemann-Roch spaces.

2.4 Algebraic plane curves over finite fields

Let p be a prime and K an algebraically closed field of characteristic p. For $q = p^e$ we define the *Frobenius automorphism* $\operatorname{Frob}_q: x \mapsto x^q$ of K. This extends to an Frobenius map of K-polynomials (acting on the coefficients) and of affine and projective points over K (acting on the coordinates). The curve X is said to be \mathbb{F}_q -rational, if it is Frob_q -invariant. Moreover, the Frobenius action extends to places and divisors of \mathbb{F}_q -rational curves, which allows us to speak of places and divisors defined over

 \mathbb{F}_q . Let X be an algebraic plane curve over \mathbb{F}_q and P a place of X. Let r be the smallest positive integer such that P is defined over \mathbb{F}_{q^r} . Then, the divisor

$$P + P^{\operatorname{Frob}_q} + P^{\operatorname{Frob}_q^2} + \dots + P^{\operatorname{Frob}_q^{r-1}}$$

is an \mathbb{F}_q -rational place of degree r of X.

If A is an \mathbb{F}_q -rational divisor then the Riemann-Roch space $\mathscr{L}(A)$ has a basis which consists of \mathbb{F}_q -rational elements of the function field of X. Hence, we can view $\mathscr{L}(A)$ as an \mathbb{F}_q -linear space of dimension $\ell(A)$. Similarly, $\Omega(A)$ can be seen as a vector space over \mathbb{F}_q .

If X is an algebraic curve over \mathbb{F}_q and α is an automorphism of X, then we say that α is defined over \mathbb{F}_q provided α commutes with the Frobenius map Frob_q . The automorphisms of X which are defined over \mathbb{F}_q form a subgroup of $\operatorname{Aut}(X)$.

2.5 Algebraic-geometry codes

Algebraic-geometry (AG) codes are linear codes constructed from algebraic curves defined over a finite field \mathbb{F}_q . The best known such general construction was originally introduced by Goppa, see [Gop88]. It provides linear codes from certain rational functions whose poles are prescribed by a given \mathbb{F}_q -rational divisor G, by evaluating them at some set of \mathbb{F}_q -rational places disjoint from supp(G). The dual to such a code can be obtained by computing residues of differential forms. The former are the *functional* codes, and the latter are the *differential* codes.

Let X be a smooth plane curve defined over the finite field \mathbb{F}_q . Write $D = Q_1 + \ldots + Q_n$ for the \mathbb{F}_q -rational places Q_1, \ldots, Q_n . Let G be another divisor of $\mathbb{F}_q(X)$ whose support supp(G) contains none of the places Q_i with $1 \le i \le n$. For any function $h \in \mathcal{L}(G)$, the *evaluation* of h at D is given by

$$ev_D(h) = (h(O_1), \dots h(O_n)).$$

This defines the *evaluation map* $\operatorname{ev}_D: \mathscr{L}(G) \to \mathbb{F}_q^n$ which is \mathbb{F}_q -linear and also injective when $n > \deg(G)$. Therefore, its image is a subspace of the vector space \mathbb{F}_q^n , or equivalently, an AG [n,k,d]-code where $d \geq n - \deg(G)$ and if $\deg(G) > 2g - 2$ then $k = \deg(G) + 1 - g$. Such a code is the *functional* code

$$C_L(D,G) = \{ (h(Q_1), \dots, h(Q_n)) \mid h \in \mathcal{L}(G) \}$$

with designed minimum distance $n - \deg(G)$. The dual code

$$C_{\Omega}(D,G) = \{ (\operatorname{res}_{O_1}(dh), \dots, \operatorname{res}_{O_1}(dh)) \mid dh \in \Omega(G-D) \}$$

of $C_L(D,G)$ is named a differential code. The differential code $C_{\Omega}(D,G)$ is a $[n,\ell(G-D)-\ell(G)+\deg D,d]$ -code with $d \geq \deg(G)-(2g-2)$, and its designed minimum distance is $\deg(G)-(2g-2)$.

Typically the divisor G is taken to be a multiple mP of a single place P of degree one. Such codes are the *one-point* codes, and have been extensively investigated. It has been shown however that AG-codes with better parameters than the comparable one-point Hermitian code may be obtained by allowing the divisor G to be more general, see [MM05] and the references therein.

2.6 Hermitian curves over finite fields

This package implements places, divisors and Riemann-Roch spaces of the *Hermitian curve* H_q defined over \mathbb{F}_{q^2} . We quote the most important geometric and combinatorial properties of H_q , the refer-

ences are [Hir98] and [HP73]. In the projective plane $PG(2, \mathbb{F}_{q^2})$ equipped with homogeneous coordinates (X:Y:Z), a canonical form of H_q is $X^{q+1}-Y^qZ-YZ^q=0$ so that

$$H_q: X^{q+1} = Y^q + Y$$

in the affine equation. Every \mathbb{F}_{q^2} -rational place of the function field $\mathbb{F}_{q^2}(H_q)$ of H_q corresponds to a point of H_q in $PG(2,\mathbb{F}_{q^2})$, and this holds true for the degree one places of the constant field extension $\mathbb{F}_{q^{2k}}(H_q)$ which correspond to the points of H_q in $PG(2,\mathbb{F}_{q^{2k}})$. Moreover, a place P of degree r>1 of $\mathbb{F}_{q^2}(H_q)$ is represented by a divisor $P_1+P_2+\ldots+P_r$ of the constant field extension $\mathbb{F}_{q^{2r}}(H_q)$ where P_i are degree one places of $\mathbb{F}_{q^{2r}}(H_q)$ with $P_i=P_1^{\operatorname{Frob}_{q^2}}$ for $i=0,1,\ldots,r-1$. Furthermore,

$$|H_q(\mathbb{F}_{q^2})| = |H_q(\mathbb{F}_{q^4})| = q^3 + 1$$

and

$$|H_q(\mathbb{F}_{q^6})| = q^6 + 1 + q^4(q-1),$$

where $H_q(K)$ denotes the set of K-rational points of the projective curve H_q . A line l of $PG(2, \mathbb{F}_{q^2})$ is either a tangent to H_q at an \mathbb{F}_{q^2} -rational point of H_q or it meets H_q at q+1 distinct \mathbb{F}_{q^2} -rational points. In terms of intersection divisors, see \cite[Section 6.2]{HKT_book},

$$I(H_a, l) = (q+1)Q$$

for the point $Q \in H_q(\mathbb{F}_{q^2})$ of tangent l of H_q , and

$$I(H_q, l) = \sum_{i=1}^{q+1} Q_i$$

for the q+1 distinct points of intersections Q_1, \ldots, Q_{q+1} of l and H_q .

Through every point $V \in PG(2,\mathbb{F}_{q^2})$ not in $H_q(\mathbb{F}_{q^2})$ there are q^2-q+1 secants and q+1 tangents to H_q . The corresponding q+1 tangency points are the common points of H_q with the polar line of V relative to the unitary polarity associated to H_q . Let V=(1:0:0). Then the line l_∞ of equation Z=0 is tangent at $P_\infty=(0:1:0)$ while another line through V with equation Y-cZ=0 is either a tangent or a secant according as c^q+c is 0 or not.

If K is the algebraic closure of \mathbb{F}_{q^2} with q > 2, then the group of K-automorphisms of the Hermitian curve H_q is the projective unitary group PGU(3,q). In particular, all automorphisms of H_q are defined over \mathbb{F}_{q^2} . The automorphism group act doubly transitively on the set of \mathbb{F}_{q^2} -rational points.

Chapter 3

How to use the package

3.1 Hermitian curves

The following functions are available:

3.1.1 IsHermitian_Curve

▷ IsHermitian_Curve(obj)

(Category)

Hermitian curve H(q) is an algebraic curve over an algebraically closed field, having an affine equation $X^{q+1} = Y^q + Y$. The base field of H(q) is $GF(q^2)$.

3.1.2 Hermitian_Curve

(operation)

Returns: The corresponding Hermitian curve H(q) over the algebraic closure of the field K. The indeterminates X,Y of hratfn generate the corresponding Hermitian function field K(X,Y) such that $X^{q+1}=Y^q+Y$. K must be a finite field of square order. The points of H(q) are either affine P(a,b) satisfying $a^{q+1}=b^q+b$, or the infinite point [infinity]. One can use the in operation to test if a point lies on the Hermitian curve.

3.1.3 IndeterminatesOfHermitian_Curve

▷ IndeterminatesOfHermitian_Curve(Hq)

(function)

Returns: The indeterminates of the function field of the Hermitian curve *C*.

3.1.4 Genus

▷ Genus (Hq) (attribute)

The genus of the Hermitian curve H(q) is q(q-1)/2.

3.1.5 UnderlyingField

▷ UnderlyingField(Hq)

(attribute)

The underlying field of a Hermitian curve is the field of coefficients of the corresponding algebraic function field, it is a finite field of square order.

3.1.6 AllRationalAffinePlacesOfHermitian_Curve

```
▷ AllRationalAffinePlacesOfHermitian_Curve(Hq)
```

(operation)

Returns: All rational affine places of the Hermitian curve Hq. The number of rational affine places of H(q) is q^3 .

3.1.7 AllRationalPlacesOfHermitian_Curve

```
▷ AllRationalPlacesOfHermitian_Curve(Hq)
```

(operation)

Returns: All rational places of the Hermitian curve Hq. Here, a place is a 1-point divisor of degree one, that is, defined over $GF(q^2)$. Notice that the place at infinity is rational. The number of rational places of H(q) is $q^3 + 1$.

3.1.8 RandomRationalPlaceOfHermitian_Curve

▷ RandomRationalPlaceOfHermitian_Curve(Hq)

(operation)

Returns: A random rational place of the Hermitian curve Hq. Here, a place is a 1-point divisor of degree one, that is, defined over $GF(q^2)$. Notice that the place at infinity is rational.

3.1.9 RandomPlaceOfGivenDegreeOfHermitian_Curve

▷ RandomPlaceOfGivenDegreeOfHermitian_Curve(Hq, d)

(operation)

Returns: A random place of degree d of the Hermitian curve Hq, that is, a place defined over the field $GF(q^{2d})$. Notice that the place at infinity has degree 1.

```
___ Example __
gap> q:=5;
gap> Y:=HermitianIndeterminates(GF(q^2), "Y1", "Y2");
[ Y1, Y2 ]
gap> Hq:=Hermitian_Curve(Y[1]);
<Hermitian curve over GF(25) with indeterminates [ Y1, Y2 ]>
gap> UnderlyingField(Hq);
gap> p:=RandomPlaceOfGivenDegreeOfHermitian_Curve(Hq,3);
<Hermitian place [ Z(5^6)^12002, Z(5^6)^14911 ] over indeterminates [ Y1, Y2 ]>
gap> p in Hq;
true
gap> [ infinity ] in Hq;
true
gap> [0,0] in Hq;
false
gap > Z(q) * [0,0] in Hq;
gap> Size( AllRationalPlacesOfHermitian_Curve(Hq) );
126
```

3.2 Automorphisms of Hermitian curves

3.2.1 FrobeniusAutomorphismOfHermitian_Curve

attribute)

Returns: The Frobenius automorphism of the underlying field of the Hermitian curve *Hq*. More precisely, the output is an AC-Frobenius automorphism in the sense of the package OnAlgClosure, acting on the algebraic closure of the underlying finite field.

3.2.2 IsHermitian_CurveAutomorphism

```
▷ IsHermitian_CurveAutomorphism(obj)
```

(Category)

With automorphisms of an algebraic curve C one means the automorphisms of the corresponding algebraic function field K(C). For a Hermitian curve H(q) over a finite field, Aut(GF(q)(H(q))) is isomorphic to the projective general linear group PGU(3,q). In particular, an automorphism of H(q) can be represented by a 3×3 unitary matrix over $GF(q^2)$.

3.2.3 Hermitian_CurveAutomorphism

ightharpoonup Hermitian_CurveAutomorphism(Hq, mat)

(operation)

Returns: The automorphism of the Hermitian curve H(q), given by the unitary matrix mat.

3.2.4 AutomorphismGroup

▷ UnitaryGroupToHermitian_CurveAutGroup(matgr, Hq)

(function)

Returns: the group G of automorphisms of the Hermitian curve Hq, which correspond to the unitary group matgr.

The permutation action of matgr on the set of rational places of Hq is stored as a nice monomorphism of $G. \triangleright AutomorphismGroup(Hq)$ (operation)

Returns: The automorphism group of the Hermitian curve Hq. The elements are Hermitian curve automorphisms. The group is isomorphic to PGU(3,q), where $GF(q^2)$ is the underlying field of Hq.

3.3 Hermitian divisors

The following functions are available:

3.3.1 IsHermitian_Divisor

```
▷ IsHermitian_Divisor(obj)
```

(Category)

A Hermitian divisor is a divisor of an algebraic function field of the Hermitian curve $H(q): X^{q+1} = Y^q + Y$. Hermitian divisors form an additive commutative group.

3.3.2 IsHermitian_Place

▷ IsHermitian_Place(obj)

(filter)

In this implementation, a Hermitian place is a Hermitian divisor of degree one and support length one.

3.3.3 Hermitian_DivisorConstruct

▷ Hermitian_DivisorConstruct(Hq, pts, ords)

(function)

Returns: The Hermitian divisor over *Hq* with (projective) points from *pts* and corresponding orders from *ords*. It checks the input.

3.3.4 IndeterminatesOfHermitian_Divisor

▷ IndeterminatesOfHermitian_Divisor(D)

(function)

Returns: The pair of indeterminates of the function field of the Hermitian divisor D.

3.3.5 Hermitian_Divisor

▷ Hermitian_Divisor(Hq, pts, ords)

(operation)

(operation)

Returns: The corresponding Hermitian divisor over the Hermitian curve Hq. The list pts must be points of Hq; the infinite point is [infinity]. The list ords contains the respective orders. The elements of the list pairs are the point-order pairs.

3.3.6 Hermitian_Place

▷ Hermitian_Place(Hq, pt)

(operation)

Returns: The corresponding place of the Hermitian curve Hq, where pt is either an affine point Hq, or the infinite point [infinity].

3.3.7 ZeroHermitian_Divisor

▷ ZeroHermitian_Divisor(Hq)

(operation)

Returns: The zero divisor over the Hermitian curve Hg.

3.3.8 SupremumHermitian_Divisor

▷ SupremumHermitian_Divisor(D1, D2)

(function)

Returns: The place-wise maximum of the orders of D1 and D2.

3.3.9 InfimumHermitian_Divisor

▷ InfimumHermitian_Divisor(D1, D2)

(function)

Returns: The place-wise minimum of the orders of D1 and D2.

3.3.10 PositivePartOfHermitian_Divisor

▷ PositivePartOfHermitian_Divisor(D)

(function)

Returns: The positive part of the divisor *D*.

3.3.11 NegativePartOfHermitian_Divisor

▷ NegativePartOfHermitian_Divisor(D)

(function)

Returns: The negative part of the divisor *D*.

3.3.12 UnderlyingField

▷ UnderlyingField(D)

(attribute)

The underlying field of a Hermitian divisor is the field of coefficients of the corresponding Hermitian curve.

3.3.13 Support

▷ Support(D)

(attribute)

The support of a Hermitian divisor is the set of points with nonzero orders.

3.3.14 Valuation

 \triangleright Valuation(D, pt)

(operation)

The valuation of a Hermitian divisor D at the point or place pt is its corresponding order.

3.3.15 Value

▷ Value(f, pl)

(operation)

Returns: The value of a Hermitian rational function f at the place p1.

3.3.16 IsRationalHermitian Divisor

▷ IsRationalHermitian_Divisor(D)

(attribute)

Returns: True if D is invariant under the Frobenius automorphism of the underlying Hermitian curve.

3.3.17 PrincipalHermitian_Divisor

 \triangleright PrincipalHermitian_Divisor(Hq, f)

(operation)

Returns: The principal divisor of the rational function f of the Hermitian curve Hq.

3.3.18 IsInfiniteHermitian_Place

▷ IsInfiniteHermitian_Place(p)

(attribute)

Returns: True if *p* is a Hermitian place at the infinite line.

```
Example
gap> p_infty:=Hermitian_Place(Hq,[infinity]);
<Hermitian place [ infinity ] over indeterminates [ Y1, Y2 ]>
gap> d:=3*p_infty-4*p;
<Hermitian divisor with support of length 2 over indeterminates [ Y1, Y2 ]>
gap> Support(d);
[ [ infinity ], [ Z(5<sup>6</sup>)<sup>12002</sup>, Z(5<sup>6</sup>)<sup>14911</sup> ] ]
gap> UnderlyingField(d);
GF(5<sup>2</sup>)
gap> Zero(d);
<Hermitian divisor with support of length 0 over indeterminates [ Y1, Y2 ]>
gap> Characteristic(d);
gap>
gap> Valuation(d,p);
gap> Valuation(d,[1,2]);
gap>
gap> fr:=FrobeniusAutomorphismOfHermitian_Curve(Hq);
AC_FrobeniusAutomorphism(5^2)
gap> d^fr;
<Hermitian divisor with support of length 2 over indeterminates [ Y1, Y2 ]>
gap> Support(d^fr);
[ [ infinity ], [ Z(5^6)^3194, Z(5^6)^13423 ] ]
gap> Support(d);
[ [ infinity ], [ Z(5<sup>6</sup>)<sup>12002</sup>, Z(5<sup>6</sup>)<sup>14911</sup> ] ]
```

3.4 Hermitian Riemann-Roch spaces

3.4.1 Hermitian_RiemannRochSpaceBasis

(function

Returns: A BASIS of the Riemann-Roch space of the Hermitian divisor D, which is defined by $\{f \in K[Y] \mid Div(f) \ge -D\}$.

```
15),

3.5 Hermitian AG-codes

The following functions are available:

3.5.1 IsHermitian_Code

A Hermitian code is an algebraic-geometric (AG) code defined on the Hermitian curve of equation $X^{q+1} = Y^q + Y$. AG-codes are either of functional or of differential type.

3.5.2 GeneratorMatrixOfFunctionalHermitian_CodeNC

Returns: The generator matrix of the functional AG code $C_L(D,G)$, where D is the sum of the degree one places in the list pls. The support of G must be disjoint from pls.

3.5.3 Hermitian_FunctionalCode

```
ightharpoonup Hermitian_FunctionalCode(G, D) (operation)

ightharpoonup (operation)
```

Returns: The functional AG code $C_L(D,G) = \{(f(P_1),\ldots,f(P_n)) \mid f \in L(G)\}$. D and G are rational divisors of the Hermitian curve H(q). $D = P_1 + \cdots + P_n$, where P_1,\ldots,P_n are degree one places of H(q). The supports of D and G are disjoint. If D is not given then it is the sum of affine rational places of H(q), not contained in the support of G. By the Riemann-Roch theorem, functional codes have dimension at least $\deg(G) + 1 - g$, with equality if $\deg(G) > 2g - 2$.

3.5.4 Hermitian_DifferentialCode

```
ightharpoonup Hermitian_DifferentialCode(G, D) (operation)

ightharpoonup (operation)
```

Returns: The differential AG code $C_{\Omega}(D,G) = \{res_{P_1}(\omega), \dots, res_{P_n}(\omega) \mid \omega \in \Omega(G-D)\}$. D and G are rational divisors of the Hermitian curve H(q). $D = P_1 + \dots + P_n$, where P_1, \dots, P_n are degree one places of H(q). The supports of D and G are disjoint. If D is not given then it is the sum of affine rational places of H(q), not contained in the support of G. By the Riemann-Roch theorem, functional codes have dimension $\deg(G) + 1 - g$. The differential code is the dual of the corresponding functional code. By the Riemann-Roch theorem, differential codes have dimension at least $n - \deg(G) - 1 + g$, with equality if $\deg(G) > 2g - 2$.

3.5.5 UnderlyingCurveOfHermitian_Code

3.5.6 UnderlyingField

```
\triangleright UnderlyingField(C) (attribute)
```

The underlying field of an AG code is its left acting domain.

3.5.7 Length

```
\triangleright Length (C) (attribute)
```

Returns: The length of the AG code C.

3.5.8 GeneratorMatrixOfHermitian_Code

 \triangleright GeneratorMatrixOfHermitian_Code(C) (attribute)

Returns: The generator matrix of the AG code *C* in CVEC matrix format.

3.5.9 DesignedMinimumDistance

```
▷ DesignedMinimumDistance(C)
```

(attribute)

Returns: The designed minimum distance δ of the Hermitian AG code C. When $\deg(G) \ge 2g - 2$, then the general formulas for δ are as follows. For the functional code $C_L(D,G)$, $\delta = n - \deg(G)$, and for the differential code $C_\Omega(D,G)$, $\delta = \deg(G) - (2g - 2)$.

3.5.10 Hermitian DecodeToCodeword

(operation)

Let δ be the designed minimum distance of C, and define $t = [(\delta - 1 - g)/2]$. If there is a codeword $c \in C$ with $d(c, w) \le t$ then c is returned. Otherwise, the output is fail.

The decoding algorithm is from [Hoholdt-Pellikaan 1995]. The function Hermitian_DECODER_DATA precomputes two matrices which are stored as attributes of the AG code. The decoding consists of solving linear equations.

3.6 Utilities for Hermitian AG-codes

3.6.1 InfoHermitian

□ InfoHermitian (info class)

An infoclass for the package. Its default value is 0. With SetInfoLevel(InfoHermitian,2) one can get some additional messages about the ongoing computation of Hermitian curves and their codes.

3.6.2 RestrictVectorSpace

▷ RestrictVectorSpace(V, F)

(function)

Let K be a field and V a linear subspace of K^n . The restriction of V to the field F is the intersection $V \cap F^n$.

3.6.3 UPolCoeffsToSmallFieldNC

▷ UPolCoeffsToSmallFieldNC(f, q)

(function)

This non-checking function returns the same polynomial as f, making sure that the coefficients are in GF(q).

3.6.4 RandomVectorOfGivenWeight

▷ RandomVectorOfGivenWeight(F, n, k)

(function)

Returns: A random vector of F^n of Hamming weight k.

(function)

Returns: A random vector of F^n in which the density of nonzero elements is approximatively δ .

⊳ RandomBinaryVectorOfGivenWeight(n, k)

(function)

Returns: A random vector of $GF(2)^n$ of Hamming weight k.

(function)

Returns: A random vector of $GF(2)^n$ in which the density of nonzero elements is approximatively δ .

Chapter 4

An example: Parameters of subfield subcodes of 1-point Hermitian codes

The following example computes the parameters of subfield subcodes of 1-point Hermitian codes.

```
Example
gap > q:=4; r:=2;
gap> Y:=HermitianIndeterminates(GF(q^2), "Y1", "Y2");
[ Y1, Y2 ]
gap> Hq:=Hermitian_Curve(Y[1]);
<Hermitian curve over GF(16) with indeterminates [ Y1, Y2 ]>
gap> P_infty:=Hermitian_Place(Hq,[infinity]);
